Project Overview: Static HTML Deployment to PaaS

Objective:
The primary goal of this project is to demonstrate the process of deploying a web application to a **Platform as a Service (PaaS)** environment. While the project itself is a static HTML/CSS website, the focus is on mastering the DevOps workflow, cloud integration, and automated hosting.

Key Learning Outcomes:

- **Infrastructure Abstraction:** Understanding how PaaS removes the need to manage physical servers, operating systems, or web server configurations (like Nginx or Apache).
- **Deployment Workflow:** Setting up a connection between a Version Control System (GitHub/GitLab) and a cloud provider.
- **Continuous Deployment (CD):** Implementing "Push-to-Deploy" mechanics, where every update to the repository is automatically reflected on the live URL.
- **Environment Configuration:** Managing basic cloud settings, such as custom domains, SSL certificates, and scaling parameters.

Tools Used:

- **Frontend:** HTML5, CSS3.
- **Version Control:** Git & GitHub.
- **PaaS Provider:** [Укажи платформу, например: Vercel / Netlify / Render / GitHub Pages].

Conclusion:
This project serves as a foundational step in understanding cloud-native development. By abstracting the infrastructure, PaaS allows for rapid prototyping and ensures that the application is accessible via a stable, global production URL.
